

8-bit **AVR**[®]
RISC
Microcontroller

Application
Note

AVR 305: Half Duplex Compact Software UART

Features

- 32 Words of Code, Only
- Handles Baud Rates of up to 38.4 kbps with a 1 MHz XTAL
- Runs on Any AVR Device
- Only Two Port Pins Required
- Does Not Use Any Timer

Introduction

In many applications utilizing serial communication, the software handling communication does not have to be performed as a background task. This application note describes how to implement a polled software UART capable of handling speeds up to 614,400 bps on an AT90S1200. This implementation is intended for applications where small code is preferred. All bit delays are software delays, so no timer is required. The controller can not perform any other tasks while receiving or transmitting, but when the operation is complete, the controller is free to continue program execution.

Theory of Operation

In asynchronous serial communication, no clock information is transferred. The data is transferred serially, one bit at a time. In Idle state, the line is held at logical "1". When data is to be transferred, the first bit is a so called start bit, often given the symbol S. The start bit is a "0", causing a "1" to "0" transition at the line. This can be detected by the receiver, signaling that data is coming. The following bits transferred are the data bits, with the LSB first. Then, one or more stop bits (P) are transferred. The stop bit is a logical "1", putting the line back to idle state before a new start bit followed by a data byte can be transferred. There must be at least one stop bit, so that a "1" to "0" transition can be detected by the receiver, indicating a new start bit. The *frame* shown in Figure 1 has got eight data bits and one stop bit. Sometimes, a parity bit is included between the last data bit and the stop bit, and there can be several stop bits.

Figure 1. Frame Format

The Receiver must sample the data line in the middle of every bit in order to receive the data properly. The bit length has to be equal for all bits, so that the Receiver knows when to sample the line. The Receiver is synchronized with the Transmitter by the falling edge of the start bit. The Receiver must have an internal timer in order to sample the bits at the right time.

The bit length must be the same for both transmitter and receiver, and some standard speeds are defined in bits per second, *bps*.

Rev. 0952B-AVR-05/02

Implementation

Bit Length Delays - *UART_delay*

The delay between the bits are generated by calling a delay subroutine twice (as the subroutine generates a half-bit delay, see receiving data). If very short delays are required (when transmitting and receiving at very high speed), the delay must be implemented inside the *putchar* and *getchar* routines. The required delay length in clock cycles can be calculated using the following formula:

$$c = \frac{f_{CLCL}}{\text{baud rate}}$$

where c is the bit length in clock cycles and f_{CLCL} is the crystal frequency.

Both *putchar* and *getchar* use nine CPU cycles to send or receive a bit. Hence, a delay of $c - 9$ cycles must be generated between each bit. The *rcall* and *ret* instructions require a total of seven cycles. If the subroutine is to be called twice to generate the required delay, the delay has to be d cycles:

$$d = \frac{c - 9}{2} - 7$$

If the delay is generated as shown below, the total execution time is $3 \cdot b$ cycles plus seven cycles for *rcall* and *ret*.

```

                rcall    UART_delay
UART_delay:    ldi      temp,b
UART_delay1:  dec       temp
                brne    UART_delay1
                ret
    
```

The value b is found by the equation

$$b = \frac{\frac{c - 9}{2} - 7}{3} = \frac{c - 23}{6}$$

The actual delay generated, calling *delay* twice is

$$d = (3 \times b + 7) \times 2 + 9 = 6 \times b + 23$$

From this, the minimum and maximum delays are $d_{min} = 29$ and $d_{max} = 1,559$ cycles. The c and b values for some bit rates and frequencies are shown in Table 8.

Table 1. “UART_delay” Subroutine Performance Figures

| Parameter | Value |
|------------------|--|
| Code Size | 4 words |
| Execution Cycles | Min: 7 cycles Max: 772 cycles (including <i>ret</i>) |
| Register Usage | <ul style="list-style-type: none"> • Low registers • High registers • Global <div style="display: flex; justify-content: flex-end; align-items: center; gap: 10px;"> :None :None :1 </div> |

Table 2. “UART_delay” Register Usage

| Register | Input | Internal | Output |
|----------|-------|-------------------------|--------|
| R17 | – | “temp” - count variable | – |

Transmitting Data - *putchar*

The *putchar* subroutine transmits the byte stored in the register *Txbyte*. The data bits are shifted into the Carry bit. The easiest way to generate stop bits is to let the zeros shifted into the transmitted byte be interpreted as ones. If the data byte is inverted before it is shifted, a "0" in Carry must give a "1" on the line, and a "0" in Carry gives a "1" on the line. When 0's are shifted into the data byte, they are handled as 1's. This way, any number of stop bits can be generated by just repeating the transmittal loop. The start bit is generated by setting the carry bit before data are shifted out.

Table 3. “putchar” Subroutine Performance Figures

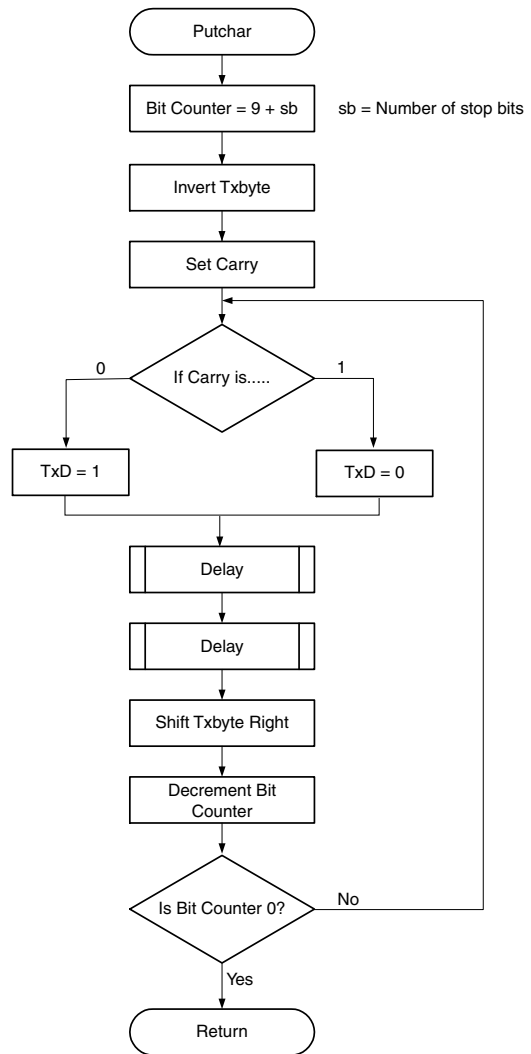

| Parameter | Value |
|------------------|--|
| Code Size | 14 words |
| Execution Cycles | Depends on bit rate |
| Register Usage | <ul style="list-style-type: none"> • Low registers :None • High registers :None • Global :2 |

Table 4. “putchar” Register Usage

| Register | Input | Internal | Output |
|----------|-----------------------------|--|--------|
| R16 | – | “bitcnt” – counts the number of bits transferred | – |
| R18 | “Txbyte” – the byte to send | – | – |

The algorithm for transmitting data is shown in Figure 2.

Figure 2. *putchar* Subroutine

Receiving Data - *getchar*

First, the routine waits for a logical "0" (not a transition). When the start bit is detected, a 1.5 bit delay is generated. This is performed by calling the delay subroutine three times. Sampling then starts at 1-bit intervals. The Carry is set or cleared according to the logic value at the RxD pin. If less than eight data bits are received, the Carry is shifted into the receive byte. If not, the routine returns with the received byte in *Rxbyte*.

The routine waits for one bit length after the last data bit and terminates in the middle of the stop bit. This is done to prevent detection of a false startbit if the routine is called again immediately after a complete reception.

Table 5. "getchar" Subroutine Performance Figures

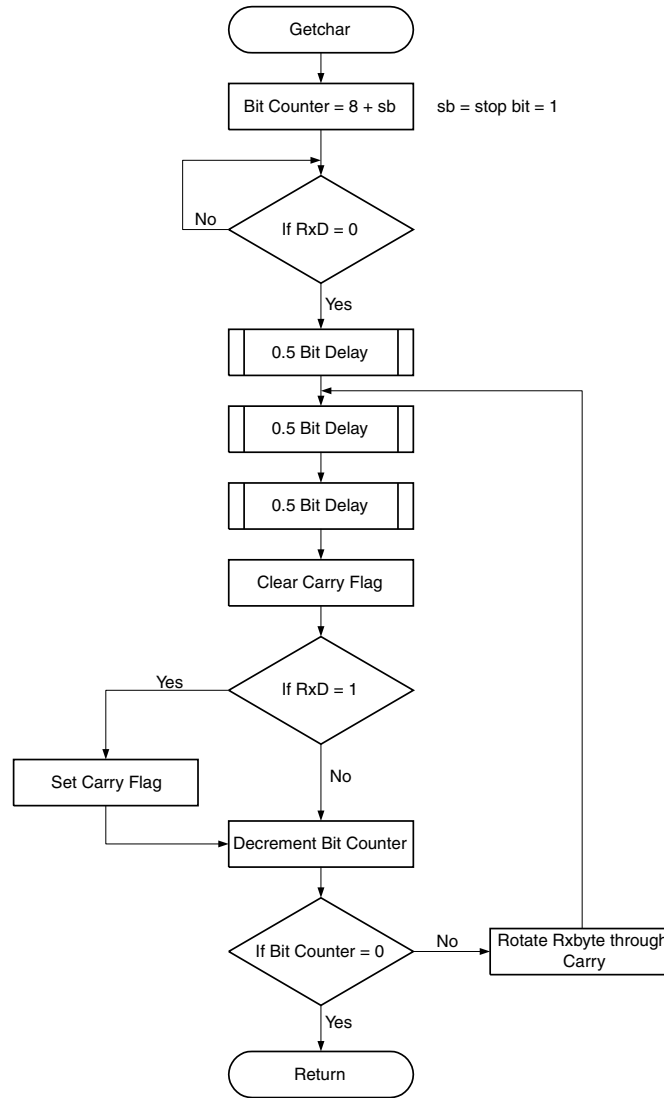

| Parameter | Value |
|------------------|--|
| Code Size | 14 words |
| Execution Cycles | Waits until byte received |
| Register Usage | <ul style="list-style-type: none"> • Low registers :None • High registers :None • Global :2 |

Table 6. "getchar" Register Usage

| Register | Input | Internal | Output |
|----------|-------|---|-----------------------------|
| R16 | – | "bitcnt" – counts the number of bits received | – |
| R18 | – | – | "Rxbyte" –the received byte |

The algorithm for receiving data is shown in Figure 3.

Figure 3. *getchar* Subroutine

Example Program

The example program receives a character with *getchar* and echoes it back with *putchar*.

Table 7. Overall Performance Figures

| Parameter | Value |
|------------------|--|
| Code Size | 32 words - UART routines only 40 words - Complete application note |
| Register Usage | <ul style="list-style-type: none"> • Low registers :None • High registers :4 • Global :None |
| Interrupt Usage | None |
| Peripheral Usage | Port D pin 0 and 1 (any two pins can be used) |

Table 8. Baud Rate Table
