

5W AUDIO AMPLIFIER WITH MUTING

DESCRIPTION

The TDA1905 is a monolithic integrated circuit in POWERDIP package, intended for use as low frequency power amplifier in a wide range of applications in radio and TV sets:

- muting facility
- protection against chip over temperature
- very low noise
- high supply voltage rejection
- low "switch-on" noise
- voltage range 4V to 30V

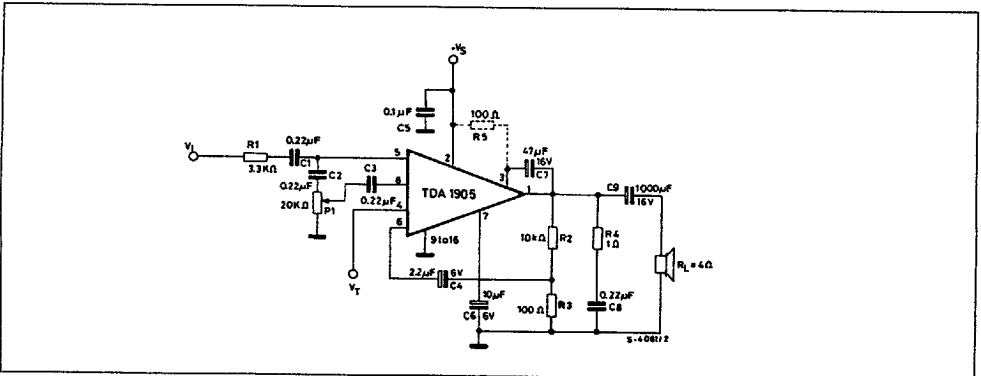

The TDA 1905 is assembled in a new plastic package, the POWERDIP, that offers the same assembly ease, space and cost saving of a normal dual in-line package but with a power dissipation of up to 6W and a thermal resistance of 15°C/W (junction to pins).

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Value	Unit
V_s	Supply voltage	30	V
I_o	Output peak current (non repetitive)	3	A
I_o	Output peak current (repetitive)	2.5	A
V_i	Input voltage	0 to + V_s	V
V_i	Differential input voltage	± 7	V
V_{11}	Muting threshold voltage	V_s	V
P_{tot}	Power dissipation at $T_{amb} = 80^\circ\text{C}$	1	W
	$T_{case} = 60^\circ\text{C}$	6	W
T_{stg}, T_j	Storage and junction temperature	-40 to 150	$^\circ\text{C}$

MUTING FUNCTION

The output signal can be inhibited applying a DC voltage V_T to pin 4, as shown in fig. 29

Figure 29

The input resistance at pin 5 depends on the threshold voltage V_T at pin 4 and is typically :

$R_5 = 200 \text{ K}\Omega$	@	$1.9\text{V} \leq V_T \leq 4.7\text{V}$	muting-off
$R_5 = 10 \text{ }\Omega$	@	$0\text{V} \leq V_T \leq 1.3\text{V}$	muting-on
		$6\text{V} \leq V_T \leq V_s$	muting-on

Referring to the following input stage, the possible attenuation of the input signal and therefore of the output signal can be found using the following expression:

$$A_T = \frac{V_i}{V_8} = \frac{R_g + \left(\frac{R_8 \cdot R_5}{R_8 + 5} \right)}{\left(\frac{R_8 \cdot R_5}{R_8 + R_5} \right)}$$

where $R_8 \cong 100 \text{ K}\Omega$

Considering $R_g = 10 \text{ K}\Omega$ the attenuation in the muting-on condition is typically $A_T = 60 \text{ dB}$. In the muting-off condition, the attenuation is very low, typically 1.2 dB.

A very low current is necessary to drive the threshold voltage V_T because the input resistance at pin 4 is greater than $150 \text{ K}\Omega$. The muting function can be used in many cases, when a temporary inhibition of the output signal is requested, for example:

- in switch-on condition, to avoid preamplifier power-on transients (see fig. 22)

- during switching at the input stages.
- during the receiver tuning.

The variable impedance capability at pin 5 can be useful in many applications and two examples are shown in fig. 25 and 27, where it has been used to change the feedback network, obtaining 2 different frequency responses.

APPLICATION SUGGESTION

The recommended values of the external components are those shown on the application circuit of fig. 21. When the supply voltage V_S is less than 10V, a 100 Ω resistor must be connected between pin 2 and pin 3 in order to obtain the maximum output power. Different values can be used. The following table can help the designer.

Component	Raccom. value	Purpose	Larger than recommended value	Smaller than recommended value	Allowed range	
					Min.	Max.
$R_g + R_1$	10K Ω	Input signal imped. for muting operation	Increase of the attenuation in muting-on condition. Decrease of the input sensitivity.	Decrease of the attenuation in muting on condition.		
R_2	10K Ω	Feedback resistors	Increase of gain.	Decrease of gain. Increase quiescent current.	9 R_3	
R_3	100 Ω		Decrease of gain.	Increase of gain.		1K Ω
R_4	1K Ω	Frequency stability	Danger of oscillation at high frequencies with inductive loads.			
R_5	100 Ω	Increase of the output swing with low supply voltage.			47	330
P_1	20K Ω	Volume potentiometer	Increase of the switch-on noise.	Decrease of the input impedance and of the input level.	10K Ω	100K Ω
C_1 C_2 C_3	0.22 μ F	Input DC decoupling.	Higher cost lower noise.	Higher low frequency cutoff. Higher noise.		
C_4	2.2 μ F	Inverting input DC decoupling.	Increase of the switch-on noise.	Higher low frequency cutoff.	0.1 μ F	
C_5	0.1 μ F	Supply voltage bypass.		Danger of oscillations.		
C_6	10 μ F	Ripple rejection	Increase of SVR increase of the switch-on time	Degradation of SVR	2.2 μ F	100 μ F
C_7	47 μ F	Bootstrap.		Increase of the distortion at low frequency.	10 μ F	100 μ F
C_8	0.22 μ F	Frequency stability.		Danger of oscillation.		
C_9	1000 μ F	Output DC decoupling.		Higher low frequency cutoff.		

THERMAL SHUT-DOWN

The presence of a thermal limiting circuit offers the following advantages:

- 1) An overload on the output (even if it is permanent), or an above limit ambient temperature can be easily tolerated since the T_j cannot be higher than 150 °C.
- 2) The heatsink can have a smaller factor of safety compared with that of a conventional circuit. There is no possibility of device damage due to high junction temperature.
If for any reason, the junction temperature increases up to 150 °C, the thermal shut-down simply reduces the power dissipation and the current consumption.

The maximum allowable power dissipation depends upon the size of the external heatsink (i.e. its thermal resistance); fig. 32 shows this dissipable power as a function of ambient temperature for different thermal resistance.
